COVER
The structure of the meteorite, which has 16 percent nickel (by weight) is intermediate between a fine octahedrite and an ataxite. The large kamacite plates make up the well-defined Widmanstätten pattern typical of the octahedrites. The interior areas between the kamacite plates of the major pattern are regions of transformed taenite (plessite) which contain a micro-Widmanstätten pattern sometimes found in the ataxites. This micropattern formed late in the meteorite’s cooling history (about X 35). See pages 975 and 976. [J. I. Gold-
