Developing tylosis in the wood of Eucalyptus obliqua. In general, a
tylosis is formed by growth of a portion of a cell wall either into the
lumen of a neighboring tracheary element or into an intercellular space,
such as the duct of a resin canal. Such cellular outgrowths tend to fill
the adjacent space, thus obstructing the movement of solutions (preserva-
tives, pulping liquor) through the wood (Scale: about 1 cm = 1 micron).
