This stack of chromatograms—72 samples, 36 protein hydrolyzate runs—is what the Beckman Model 121 Amino Acid Analyzer did between Friday and Monday morning. All automatically. Nobody had to be around to turn a knob or apply a sample. And because everything is so automatic, repeatability is remarkable. Beckman also makes analyzers to handle smaller volumes of work with a little more operator involvement. All Beckman analyzers give you the same superb resolution and they're all backed by the same force of expert field service engineers. For information, write Beckman Instruments, Inc., Spinco Division, 1117 California Ave., Palo Alto, California 94304. Ask for SB-333.

Talk about a weekend's work!

This Amino Acid Analyzer does it automatically.
LETTERS

Nuclear Power Plants: How Many?

In his letter (7 Nov., p. 686), Hull calls my book The Careless Atom "a one-sided picture" of nuclear reactors, and Rossin in another letter (p. 687) recapitulates the usual arguments for nuclear plants, as though the book does not include them. It does. But the title would warn most readers that I am less impressed by these arguments than Hull and Rossin seem to be.

Hull cites "100 reactors in the United States, that operate routinely and dependably." We have heard a lot about these 100 reactors lately, and I am sure there are some utility executives who would like to know where they are. Only 17 civilian nuclear power plants (and one military plant at Hanford) had been completed by the end of 1968, when my book was printed. Of these, five had already been shut down prematurely as impracticable or unsafe; a sixth, the Fermi reactor, was never made to operate properly and finally suffered an accident which took it out of service; a seventh, the Humboldt plant, has operated within allowable radiation release limits only by reducing power output. The remainder have had various degrees of difficulty, and another was shut down this year. Only two reactors have gone into operation since my book appeared, so the situation has not changed very much.

It is therefore not clear what 100 reactors Hull is talking about, but to get such a large number he must be including the various research reactors in use in universities, as well as the reactor experiments conducted by the Atomic Energy Commission. Most of these machines share little but a name with central-station power reactors. One small research and training reactor, not dealt with in my book, caused the only deaths—three—that have occurred in the reactor program so far, but I assume this was not one of the 100 reactors whose operation so gratifies Hull.

In view of the limited operating experience with power reactors, and the failure of about half those constructed, it is hard to evaluate Hull's statistic that such reactors have kept within 1 percent of allowable radiation-release limits. The data he cites indicate that emissions increase over time, and the plants which have operated at all have achieved only a fraction of their expected lifetimes. In any case, the argument is only persuasive if one forgets that the allowable limits are set by the same agency that approves the designs of the plants in question. The standards themselves, not AEC's success in meeting its own requirements, are the source of concern.

The only point on which Hull, Rossin, and I are agreed is that the costs and risks of nuclear power should be weighed against those of other means of power generation. Only open debate will settle the merits of the various approaches that are possible. The recitation of platitudes and irrelevant numbers will not advance the debate in a useful direction.

SHELDON NOVICK

NAS Collaboration with SSRC

Unfortunately, Walsh's story ("Behavioral and social sciences: NAS report stresses applications," 31 Oct., p. 585) carries a headline which gives the impression that this was a report exclusively of the National Academy of Sciences. Although the joint sponsorship by the Academy and the Social Science Research Council is correctly mentioned in the middle of the article, the reader does not get the impression that this was a truly joint effort in every way.

Drug Detection

We know from testimony given in October in San Francisco before the House Select Committee on Crime chaired by Congressman Pepper that drugs are being diverted in alarming amounts from the manufacturers to illegal markets. This diversion requires, of course, very complex political and social "cures." However, it would help enforcement agencies if drugs were to be tagged at the manufacturing source with minute quantities of harmless isotopes (deuterium, oxygen-17, carbon-13) or with trace elements (zirconium, rare earths) which could be neutron-
activated. The tagging which would be
made a legal requirement could be done
in such a way that the "code" added
elements and quantities would vary
from batch to batch. This procedure if
followed and buttressed with proper
safeguards should interdict domestic
drug sources. It may ultimately be ap-
plied to foreign supplies by interna-
tional agreements.

Planning for PEOPLE

As an economist, I share Dubos' con-
cern ("A social design for science," 14
Nov., p. 823) that the current rate
of increase in total world industrial
output may be considerably greater
than the continuously maintainable or
"steady state" rate. Equally important,
however, is the fact that, given the
present rate of increase in population,
even this high rate of increase in total
output may not be adequate to main-
tain the existing level of per capita
output. Until the latter problem is
solved in such a way that no individual
or group is effectively excluded from
enjoying some "acceptable" minimum
standard of living, solution of the
steady state will be impossible. Aggre-
gate equilibrium with internal instabil-
ity is likely not to be an equilibrium
at all!

In support of Dubos' call for new
directions in scientific thinking, I sug-
gest that one of the things that ad-
ministrators and social scientists need
most is the cooperation of physical
and natural scientists in constructing
a "socio-ecological economics" that can
jointly consider the social, ecological,
and technical consequences, as well as
the purely economic consequences, of
proposed activities. Hopefully, such an
analytical structure would make it pos-
sible to converge over time toward
simultaneous solution of the many parts
that must be in balance in an eventual
steady state.

With luck, such a steady state might
even include the continued existence of mankind . . . and the process of
seeking it systematically might be
called "planning for PEOPLE" (Pro-
ductive Economic Opportunities in a
Pleasant Living Environment).

MODEL D

high-voltage

ELECTROPHORATOR

ELECTROPHORESIS IN ONE DIMENSION

on 18 1/4" x 22 1/4" sheets of filter paper (Chromatography may be done in second dimension). Many complex mixtures can be rapidly resolved by electrophoresis in one dimension on papers up to 4 feet long.

Developed in the Laboratory of Cellular Physiology and Metabolism, National Heart Institute, National Institutes of Health, Bethesda, Maryland. Special thanks are due to Dr. William J. Dreyer, whose co-operation and suggestions are gratefully acknowledged by Gilson Medical Electronics.

★ Easy loading with folding rack
★ 5,000 volts at 300 ma.
★ Paper immersed in bifurcated fiberglass tank containing Varsol
★ Varsol, a light petroleum fraction, has a high flash point (over 100° F.), does not conduct electricity, and has the proper degree of volatility
★ Cold tap water run through stainless steel coils at top of tank is only coolant necessary

★ Safety features:
✓ Strong, joint-free fiberglass tank eliminates electrical and fluid leaks
✓ High voltage connected to inside of tank by Nylon and stainless steel plugs attached to edge of tank
✓ Highly reliable interlock provided by an extension of the cover handle
✓ When cover is removed, high voltage is ipso facto turned off
✓ No capacitors to sneakily store electricity in apparatus

Middleton, Wisconsin 53562 • Telephone 608/836-1551

GILSON products are also manufactured in Europe:
GME • 69, Rue Gambetta → 95, Villiers-Le-Bel, FRANCE
The Willems Polytron Instruments are based on a unique design which produces unequalled results through a kinematic high-frequency system combining sonic and ultrasonic forces. This approach is so effective in inducing chemical and physical change that it has already revolutionized numerous procedures in diverse fields of research, application and production—with materials whose consistency ranges from penicillin to bauxite, in solid, semi-solid, liquid or gas forms.
