Six crystals of silicate spinel, a high-pressure mineral abundant in the transition zone of Earth's mantle, confined in a diamond-anvil cell (mount diameter, 0.45 millimeter). High-pressure x-ray studies of these crystals reveal that the MgoSiO4 end member is 13\% more compressible than the Fe2SiO4 end member even though its molar volume is 6\% less. Such anomalous compressibility suggests that the behavior of Mg2+ and Fe2+ at mantle pressures is divergent. See page 206. [Photo: R. M. Hazen]
