PRODUCTS & MATERIALS 285
Confocal microscope image of a section from an adult rat brain injected 4 weeks earlier with a human immunodeficiency virus-based vector expressing β-galactosidase (β-gal). The section was stained by immunofluorescence with antibodies to β-gal (green), the neuronal-specific marker NeuN (red), and the astrocytic protein GFAP (blue). A β-gal-expressing neuron (doubly stained, yellow) shows that the vector can transfer genes into nondividing cells, a desirable trait in gene therapy. Image width: ~240 micrometers.
