NEW VOLCANOES AND A NEW MOUNTAIN RANGE

By Professor Emeritus WILLIAM H. HOBBS
UNIVERSITY OF MICHIGAN

In Michoacan province, some two hundred miles due west of the city of Mexico, a volcano was born above a cornfield on February 20, 1943, is already more than 1,500 feet in altitude and is still in a lusty growth. It has been christened El Paricutín. The event has figured in world news, and the volcano has been visited by throngs of tourists from the city of Mexico. Already an account of this unusual event has been printed in Science (December 10, 1943) and the occurrence has been pronounced unique in history.

What is so unusual is the birth and growth of a volcanic mountain away from other volcanoes, for scores of such mountains have been observed as they have been born upon the flanks of giant volcanoes, such as Etna, and phenomena in all respects comparable to those observed at Paricutín are therefore familiar to volcanologists.

As I shall show, the birth of a volcano like Paricutín, which is some tens of miles distant from other volcanoes, is not unique. Below are listed seven such births recorded in literature, all from the Christian era, and there must have been others which are not of record:

NEW VOLCANOES (IN ORDER OF THEIR BIRTHDAYS)
Jorullo, September 28, 1759. Province of Michoacan, Mexico. 1,600 feet high. Rose above the plain of Malpais. Described by v. Humboldt in Cosmos. Fumeroles action as late as 1906.
Izalco, February 23, 1769. San Salvador. 1,900 feet

1 Strabo in his "Geography" has reported two earlier births, that of Madame during the third century b.c. and a submarine eruption in 196 B.C., both in the Aegean. Many submarine eruptions in new localities are of record, the best known that of Nwö Island (New Island), thirty miles off Cape Reykianes, Iceland, in May, 1783; and Graham Island between Sicily and Tunisia, July, 1801. Unless eruption is long continued such islands are cut away by the waves and are subsequently marked only by shoals.
