Affinity maturation selects B cells expressing somatically mutated antibody variants with improved antigen-binding properties to protect from invading pathogens. We determined the molecular mechanism underlying the clonal selection and affinity maturation of human B cells expressing protective antibodies against the circumsporozoite protein of the malaria parasite *Plasmodium falciparum* (PfCSP). We show in molecular detail that the repetitive nature of PfCSP facilitates direct homotypic interactions between two PfCSP repeat-bound monoclonal antibodies, thereby improving antigen affinity and B cell activation. These data provide a mechanistic explanation for the strong selection of somatic mutations that mediate homotypic antibody interactions after repeated parasite exposure in humans. Our findings demonstrate a different mode of antigen-mediated affinity maturation to improve antibody responses to PfCSP and presumably other repetitive antigens.

Sporozoites of the human malaria parasite *Plasmodium falciparum* (Pf) express a surface protein, circumsporozoite protein (PfCSP), with an immunodominant central NANP (Asn-Ala-Asn-Pro) repeat region (1–3). Antibodies against the repeat can mediate protection from *Plasmodium* infection in animal models (4–6). However, anti-NANP antibody-mediated protection is not readily achieved through vaccination. Thus, the induction of protective PfCSP NANP antibodies is a major goal in pre-erythrocytic vaccine development (7). We recently showed that the anti-NANP PfCSP memory B cell response in Pf-naïve volunteers after immunization with live Pf sporozoites under chloroquine prophylaxis (PfSPZ-CVac) matured predominantly through the clonal selection and expansion of potent Pf inhibitory *IGHV3-33*– and *IGKV1-5*–encoded germline antibodies with an 8-amino acid-long immunoglobulin (Ig) light chain κ complementarity-determining region 3 (CDR3) (this 8-amino acid CDR3 is hereafter designated KCDR3:8) (8, 9).

We analyzed five representative germline or low-mutated antibodies with reported affinities

for a NANP 5-mer peptide (NANP₅) between 10^{–6} and 10^{–9} M (Fig. 1A and table S1) (9). Antigen binding was abrogated when the original Ig V κ 1-5 light chain was replaced by V κ 2-28 or when the native Ig heavy chains were paired with a V κ 1-5 light chain with 9-amino acid-long KCDR3 (Fig. 1B), demonstrating the importance of these specific Ig features in antigen recognition.

All V_H3-33–V κ 1-5–KCDR3:8 antibodies were encoded by the *IGHV3-33*01* allele (9). *IGHV3-33*01* differs from three otherwise highly similar gene segments (*IGHV3-30*, *IGHV3-30-3*, and *IGHV3-30-5*) at position 52 of heavy-chain CDR2 (HCDR2), which encodes strictly a tryptophan residue and not serine or arginine (Table 1 and table S2). HCDR2 W⁵²→S (H.W52_S) and H.W52_R mutants of the selected antibodies, as well as an H.W52_A mutant of antibody 2140 and a double mutant (H.V50_F_W52_R) to mimic the *IGHV3-30*02* and *IGHV3-30-5*02* alleles, all showed reduced PfCSP repeat reactivity associated with reduced in vitro parasite inhibitory activity (Fig. 1, C and D; single-letter amino acid abbreviations are defined in the legend to Fig. 1).

The majority of NANP-reactive V_H3-33–V κ 1-5–KCDR3:8 B cells belonged to clonally expanded and somatic hypermutation (SHM)–diversified cell clusters with strong selection for replacement mutations in HCDR1 (H.S31) and HCDR2 (H.V50 and H.N56), as well as KCDR3 [KCDR3 S⁹³ (K.S93)], likely as a result of affinity maturation (Fig. 1, E and F) (9). The introduction of missing somatic mutations (mut) or reversions (rev) at H.V50 and, to a lesser extent, H.S31 revealed a role in binding to a minimal NANP₃ peptide (10, 11), as demonstrated for the germline antibody 2163 and the low-mutated antibody 1210 (Fig. 1, G and H, and table S3). In

contrast, exchanges at H.N56 and K.S93, either alone (in antibodies 1210_H.K56_N^{rev}, 1210_K.N93_S^{rev}, and 2163_H.N56_K^{mut}) or in combination (in 1210_NS and 2163_KN), showed no significant effect (Fig. 1, G and H, and table S3). Thus, affinity maturation to the repeat explained the strong selection for only two of the four characteristic replacement mutations in V_H3-33–V κ 1-5–KCDR3:8 anti-NANP antibodies.

We next determined the cocrystal structure of the 1210 antigen-binding fragment (Fab) with NANP₅ (Fig. 2, fig. S1A, and tables S4 to S6). The NANP core epitope contained a type I β turn and an elongated conformation (Fig. 2, A and C, and fig. S1B), similar to NANP bound to a chimeric 2140 Ig heavy chain–1210 Ig κ antibody and in line with previous observations (fig. S1C and tables S4 and S7) (10–14). Main-chain atoms in KCDR3 were optimally positioned to mediate H bonds with the repeat, likely contributing to the strong selection of KCDR3:8 (Fig. 2, B and C, and tables S2, S5, and S10). V_H3-33 germline residues, notably H.V50 and H.W52 (the residue encoded only by *IGHV3-33* alleles), as well as H.Y52A and H.Y58 in HCDR2, mediated the majority of antigen contacts (table S5 and fig. S2) (15). Affinity maturation at H.V50 and H.S31 may be explained by strengthened van der Waals interactions with the repeat (Fig. 2C).

Notably, our crystal structure also revealed that two 1210 Fabs (designated 1210 Fab-A and Fab-B) bound to one NANP₅ peptide in a head-to-head configuration at a 133° angle (Fig. 2D and fig. S3). This binding mode led to six homotypic antibody-antibody H bonds providing 263 Å² of buried surface area (BSA) between the two Fabs and an additional ~120 Å² of BSA between the Fabs and the repeat (Fig. 2, E and F, and tables S5, S6, and S10). Two highly selected mutations, H.N56_K and K.S93_N (Fig. 1, E and F), formed H bonds with H.Y52A and H.S99 in the opposing Fab, thereby stabilizing the head-to-head configuration (Fig. 2, G and H). KCDR3:8 optimally contacted HCDR3 of the opposite 1210 molecule, providing another explanation for the length restriction in KCDR3.

To investigate homotypic interactions, we next measured the Fab affinities for NANP₅ and NANP₃ for 1210, 1210_NS (which lacks the selected mutations involved in homotypic binding), a 1210 H.D100_Y^{mut} K.N92_Y^{mut} mutant (1210_YY, designed to disrupt head-to-head binding through steric clashes), and a 1210 germline antibody (1210_GL) (Fig. 2I and fig. S4). Compared with 1210, 1210_YY and 1210_NS showed significantly weakened affinity for NANP₅ but not for NANP₃, whereas 1210_GL was significantly worse than 1210 at binding both peptides (Fig. 2I and fig. S4) (16). These data suggest that only 1210 efficiently recognized the repeat in a high-affinity homotypic head-to-head binding configuration. An analysis of full-length PfCSP with 38 NANP repeats confirmed this hypothesis. Approximately twelve 1210 Fabs bound PfCSP and recognized the NANP repeat in a head-to-head binding configuration similar to the 1210 Fab–NANP₅ crystal structure (Fig. 2, J and K, and fig. S3D) (11, 17).

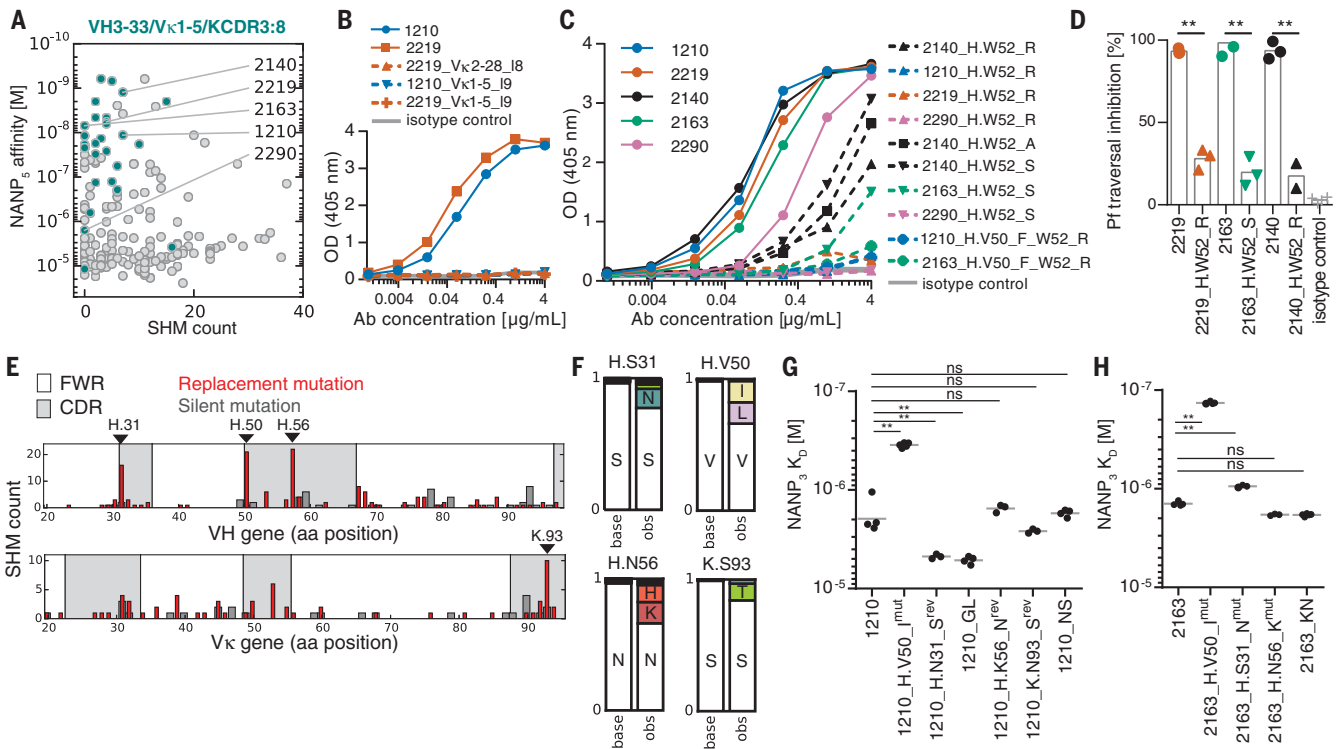

Fig. 1. Affinity maturation of high-affinity human PfCSP NANP antibodies.

(A) Surface plasmon resonance (SPR) affinity and SHM of selected (labeled) $V_{H3-33-V\kappa1-5-KCDR3:8}$ (green) and non- $V_{H3-33-V\kappa1-5-KCDR3:8}$ (gray) anti-PfCSP antibodies (9). (B to D) Original and mutated antibodies. [(B) and (C)] PfCSP enzyme-linked immunosorbent assay reactivity. Data in (A), (B), and (C) are from one experiment representative of at least two independent experiments. OD, optical density; Ab, antibody. Single-letter abbreviations for the amino acid residues are as follows: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg;

S, Ser; T, Thr; V, Val; W, Trp; and Y, Tyr. (D) Pf liver cell traversal inhibition. Bars represent means from two to four independent experiments (symbols represent results from individual experiments). $**P = 0.01$ (significant) for two-tailed Student's *t* test. (E) Silent (gray) and replacement (red) SHM (bars) in $V_{H3-33-V\kappa1-5}$ antibodies ($n = 63$). FWR, framework region; aa, amino acid. (F) Observed (obs) amino acid usage compared with a baseline (base) model (22, 23). (G and H) Independent NANP₃ SPR affinity measurements (dots) and means (gray lines). $**P = 0.01$ (significant) for Bonferroni multiple-comparisons test; ns, not significant. K_D , equilibrium dissociation constant.

Furthermore, 1210_{YY} IgG, with its restricted ability to engage in homotypic antibody interactions, showed a lower binding avidity to full-length PfCSP than 1210 (fig. S5). Thus, affinity maturation selects for mutations that improve homotypic antibody interactions, thereby indirectly increasing PfCSP NANP binding.

To better understand the selection of SHM at the cellular level, we measured the degree of B cell activation in response to NANP₅ of transgenic B cell lines expressing 1210 or variant B cell receptors (BCRs) (Fig. 3, A to D). BCR signaling was delayed in cells expressing 1210_{GL} compared with that in cells expressing 1210. This effect was even more pronounced in 1210_{YY} mutant cells. As expected, 1210_{H.V50}^{I^{mut}} (1210 with HCDR2 $V^{50} \rightarrow I$), with high repeat affinity, mediated stronger signals than 1210, especially with low antigen concentrations, whereas 1210_{NS} showed no significant differences (Fig. 3D). Thus, B cell activation is promoted by both direct NANP binding and homotypic antibody interactions. Despite a 2-log difference in NANP₃ affinities (Fig. 1, G and H) and the varied potential of these antibodies to engage in homotypic interactions, all showed similar capacities to inhibit Pf sporozoites in vitro

Table 1. HCDR2 residues encoded by different *IGHV3-33*, *IGHV3-30*, *IGHV3-30-3*, and *IGHV3-30-5* alleles. Gene and allele data are from www.imgt.org/genedb/.

Gene	Allele(s)	Residue at position			
		50	51	52	52A
<i>IGHV3-33</i>	01, 02, 03, 04, 06	V	I	W	Y
<i>IGHV3-33</i>	05	V	I	S	Y
<i>IGHV3-30</i>	01, 03, 04, 05, 06, 07, 08, 09, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19	V	I	S	Y

<i>IGHV3-30-5</i>	01	V	I	S	Y

(Fig. 3E and fig. S6). Likewise, all antibodies conferred similar levels of dose-dependent protection from the development of blood-stage parasites after passive immunization in mice, presumably because of strong avidity effects (Fig. 3F). These data provide a mechanistic explanation for the strong in vivo selection of antihomotypic antibody mutants by affinity maturation, independently of their protective efficacy as soluble antibodies.

V_{H3} antibodies dominate the anti-PfCSP memory response (9, 11, 14). In addition to $V_{H3-33-V\kappa1-5-KCDR3:8}$, we observed a cluster of highly mutated, affinity-matured $V_{H3-23-V\kappa1-5}$ NANP-reactive memory B cell antibodies in our selection (Fig. 4, A and B) (9). Although the NANP₅-binding mode of a representative $V_{H3-23-V\kappa1-5}$ antibody, 1450, was different from that of 1210, it also recognized NANP₅ in a head-to-head configuration, with HCDR3s in direct juxtaposition

Fig. 2. Affinity maturation drives homotypic repeat binding. (A to H) 1210 Fab-NANP₅ cocrystal structure. (A) Superposition of the four NANP-bound Fabs. (B) Surface representation of the antigen-antibody interaction. (C) Details of core epitope recognition by 1210. Black dashes indicate H bonds. (D) Two 1210 Fabs in complex with NANP₅. [(E) and (F)] Surface representations of Fab-B (E) and Fab-A (F). Residues involved in homotypic interactions are dark gray. [(G) and (H)] Details of homotypic interactions. Affinity-matured residues are labeled in red. (I) Mean \pm SEM K_D determined by isothermal titration calorimetry (ITC). Dots represent independent measurements. One-tailed Mann-Whitney test: * $P < 0.05$, ** $P < 0.01$. (J) Results from size exclusion chromatography coupled with multiangle light scattering (SEC-MALS) for the 1210 Fab-PfCSP complex. The red line indicates mean \pm SD molar mass from two measurements. RIU, refractive index units. (K) Two-dimensional class averages for the 1210 Fab-PfCSP complex. Red arrows indicate individual Fabs, and red lines indicate the binding angle observed in the crystal structure (D). NF54, Pf strain. Scale bar, 10 nm.

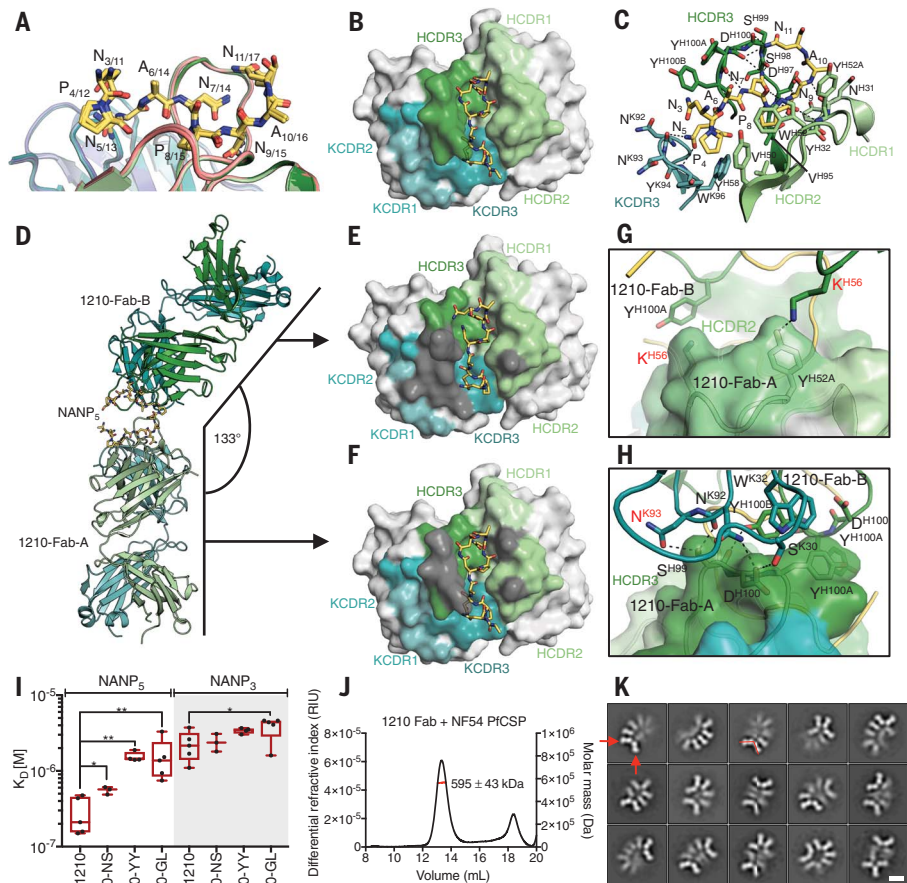

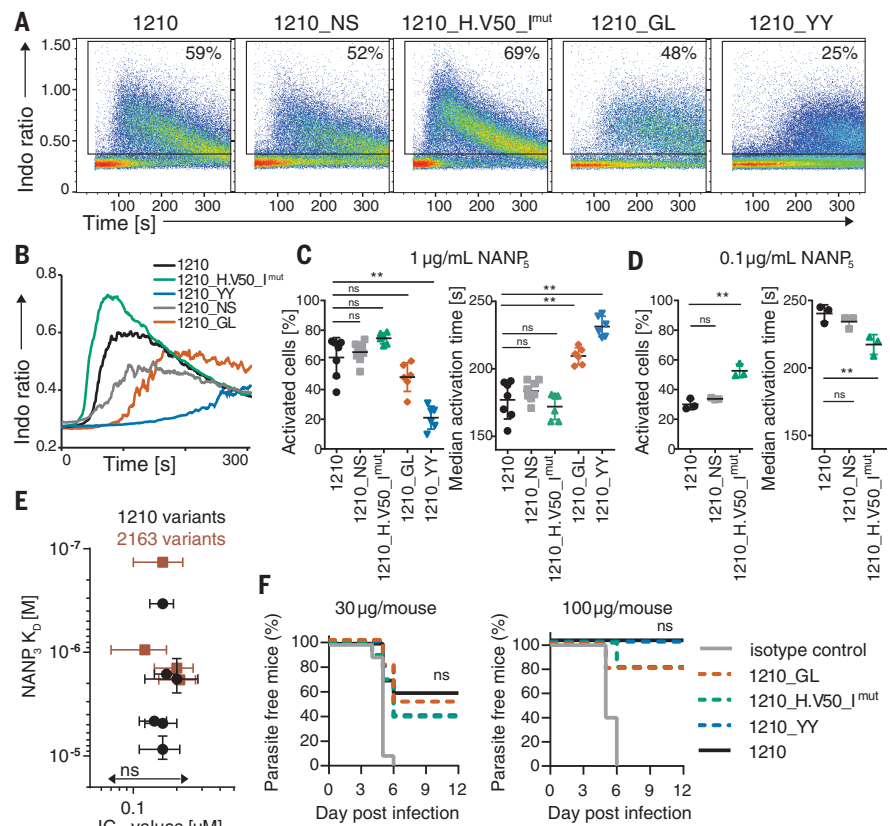

Fig. 3. B cell activation and parasite inhibition. (A to D) NANP₅-induced calcium signaling of 1210 and variants. [(A) and (B)] Reaction kinetics and percentages of activated cells (A) and overlay of median signal intensities (B) with 1 μ g/ml NANP₅ for one of at least six representative experiments. Indo, calcium indicator. [(C) and (D)] Percentages of activated cells and median activation time after the addition of 1 μ g/ml (C) ($n = 6$ or 7 experiments) and 0.1 μ g/ml (D) ($n = 3$ experiments) NANP₅. Symbols indicate results from independent experiments, and lines and error bars indicate means \pm SD. ** $P = 0.01$ (significant) for Bonferroni multiple-comparisons test. (E and F) Parasite inhibition. (E) Mean \pm SD median inhibitory concentration (IC_{50}) values from at least three independent experiments for 1210 and 2163 antibodies with indicated NANP₃ affinities. We detected no significant differences between IC_{50} values because of extensively overlapping confidence intervals. (F) Percentages of parasite-free mice after passive immunization with 30 or 100 μ g of 1210 or variants 24 hours before subcutaneous injection with *Plasmodium berghei* sporozoites expressing PfCSP (Pb-PfCSP). Data are from one (100 μ g) or two (30 μ g) independent experiments with five mice per group. We detected no significant differences in survival for 1210 variants (Mantel-Cox test).

DOI: 10.1126/science.aar5304originally published online June 7, 2018

Surface antibody maturation

Affinity maturation in B cells generates antibodies with increasingly enhanced antigen-binding properties. Imkeller *et al.* investigated the maturation of human B cells that express protective antibodies against the circumsporozoite protein of the malaria-causing parasite *Plasmodium falciparum* (PfCSP). The repetitive structure of PfCSP induces mutations in B cells, facilitating direct interactions between two repeat-bound antibodies against PfCSP, which enhance antigen affinity and B cell activation. Such interactions may optimize binding and promote clustering of surface antibodies in general.
